

ACCESSIBILITY AUDIT · WCAG 2.1 / 2.2 AA · REMEDIATION REPORT

RYT Global

Web Accessibility Audit & Remediation

A full accessibility audit and remediation pass across rytglobal.com — automated scanning, manual keyboard and screen-reader testing, root-cause code analysis, and verified fixes across five pages and the site's primary lead-capture form.

AUDITOR	D. Sonali Rao
STANDARD	WCAG 2.1 / 2.2 AA
SCOPE	5 pages + consultation modal
DATE	August 2026

TOOLS & METHODS

axe DevTools · Chrome Lighthouse · WAVE (WebAIM) · NVDA screen reader · Manual keyboard testing · Direct source-code review

HOW THIS STARTED

A Note Before the Audit

I built the RYT Global website in March 2026 — front-end structure and content, launched and live. In May 2026, I was introduced to web accessibility for the first time, and the more I learned about WCAG, the more I realized how little of it I'd actually accounted for while building.

So I turned that curiosity into a real audit — automated scanning, manual keyboard testing, a screen reader, and a full read of my own source code. What I found were major, previously invisible discrepancies: sitewide contrast failures, a lead-capture form with fifty ARIA attributes and almost no working labels, and interactive elements a screen reader couldn't even see.

This report documents that process end to end — what was broken, why, and exactly how it was fixed.

Executive Summary

This audit covered rytglobal.com in full — five public pages plus the “Request a Consultation” form shared across every one of them — evaluated against WCAG 2.1/2.2 AA using both automated scanning and hands-on manual testing. Every single surface tested started below a 6 out of 10 on WAVE's AIM accessibility score, and the shared lead-capture form scored worst of all despite being the site's primary conversion path. Rather than patching each scanner flag as an isolated bug, this audit prioritized root-cause analysis — reading the actual component and CSS source behind each failure — which traced nearly every issue back to five shared patterns rather than dozens of unrelated one-off mistakes. That distinction mattered in practice: a small number of targeted, verified fixes was enough to lift the entire site at once, rather than requiring a page-by-page rebuild.

4.8 → 9.5 average AIM score, before → after (+97%)

PAGE / SURFACE	BEFORE (AIM /10)	AFTER (AIM /10)
Home	4.7	7.7
About Us	4.6	9.8
Services	3.5	9.9
Courses	5.6	9.9
Trainers	5.6	9.8
Consultation modal	4.8	9.7

Root Causes — What Was Actually Broken, and Why

Automated scanners report symptoms. Below are the underlying causes, found by reading the actual source code rather than treating each scanner flag as an isolated bug.

01 A sitewide color token failed contrast by more than half

The `--secondary` CSS variable — used for every uppercase section label sitewide (“ABOUT US”, “OUR VISION”, “GET IN TOUCH”) — was defined at 180 47% 55%, giving roughly 2.1:1 contrast against white. WCAG AA requires 4.5:1. This single token change fixed more contrast errors than any other single fix, and disproportionately affected About Us (6 uses of the pattern) versus Services (0 uses) — exactly why About was worst-affected and Services was cleanest before this fix.

WCAG 1.4.3 · CRITICAL

02 Opacity modifiers on light text over dark/gradient backgrounds

Hero and CTA sections across every page used Tailwind opacity modifiers (`text-primary-foreground/70`, `/80`) for secondary text. Reducing white text's opacity mathematically blends it toward the background — the opposite of what's needed for contrast. Replaced with solid, contrast-verified colors sitewide.

WCAG 1.4.3 · CRITICAL

03 The sitewide lead-capture form: pervasive missing labels + ARIA overuse

The “Request a Consultation” modal — appearing on every page — had 8 missing labels, 11 orphaned labels, and 4 unlabeled dropdowns across its 20+ fields, alongside 50 separate ARIA attributes on one form. The volume of ARIA without matching visible-label wiring pointed to a UI component library generating ARIA roles and states automatically while the labels still needed manual connection — a reminder that more ARIA is not the same as correct ARIA.

WCAG 3.3.2 & 4.1.2 · CRITICAL

04 Interactive elements built as non-semantic divs

Several clickable elements (accordion triggers, a file-upload control, a modal close action) were built as `<div>/<span>` with `onClick` handlers rather than real `<button>` elements — unreachable by keyboard and announced as plain text, not controls, by screen readers.

WCAG 4.1.2 · CRITICAL

05 Dead code: two competing toast-notification systems mounted at once

The app mounted both a Radix-based toaster and an entirely separate, unused Sonner toast library simultaneously — confirmed via code that nothing in the app ever called Sonner's API. Removed as both a functional cleanup and an accessibility-DOM reduction (fewer live regions for assistive tech to track).

HYGIENE · MINOR

06 Judgment call: large stat numbers left as styled text, not real headings

WAVE flags large, bold-styled text (“17+”, “150+”) as a “possible heading.” These aren't conceptually document headings — forcing them into real heading tags would make a screen reader user's heading-navigation experience worse, not better, since they'd land on isolated numbers with no structural meaning. Left intentionally as styled paragraphs, with the reasoning documented here rather than chasing a clean scanner report at the expense of real usability.

REVIEWED • NO FIX NEEDED

Before & After: Screenshot Evidence

Live WAVE scans, captured directly — not summarized. Every number in the tables throughout this report traces back to one of these captures.

Before / After: Three Representative Fixes

Real diffs from the codebase, chosen to cover the three main categories above — contrast, labeling, and semantics.

1. Sitewide contrast token (index.css)

One CSS variable, cascading to every “eyebrow” label across the entire site. Verified against WCAG's contrast formula, not just eyeballed: 2.1:1 → 5.45:1.

BEFORE — fails 4.5:1

```
--secondary: 180 47% 55%;
```

AFTER — passes at 5.45:1

```
--secondary: 180 47% 31%;
```

2. Form labeling (Footer.tsx — newsletter signup)

Rendered on every page. The input had a placeholder only — placeholders disappear on input and aren't reliably read by all screen readers. The submit button had an icon with no accessible name at all.

BEFORE

```
<Input
  type="email"
  placeholder="Your email"
  ...
/>
<Button type="submit">
  <Send />
</Button>
```

AFTER

```
<Label htmlFor="newsletter-email" className="sr-only">
  Your email
</Label>
<Input
  id="newsletter-email"
  type="email"
  placeholder="Your email"
  ...
/>
<Button type="submit" aria-label="Subscribe to newsletter">
  <Send />
</Button>
```

3. Semantic interactivity (About.tsx — IMPACT framework accordion)

The whole card was a clickable <div> — unreachable by keyboard, silent to screen readers. Rebuilt with a real, invisibly-positioned <button> carrying the full accessible name and expanded state.

BEFORE

```
<div
  className="group ... cursor-pointer"
```

```
    onClick={() => setExpanded(...)}
    onMouseEnter={...}
  >
    <span>{item.letter}</span>
    <span>{item.title}</span>
  </div>
```

AFTER

```
<div className="group relative ..." onMouseEnter={...}>
  <button
    type="button"
    aria-label={` ${item.title}: ${item.desc}`}
    aria-expanded={expanded === i}
    className="absolute inset-0 z-10 w-full"
    onClick={() => setExpanded(...)}
  />
  <h3>{item.title}</h3>
</div>
```

Manual Testing

Automated tools typically surface only 30–40% of real WCAG issues. These two passes covered what scanners structurally cannot.

KEYBOARD NAVIGATION

95%+

Full site navigated using only Tab, Shift+Tab, Enter, and arrow keys — checking focus visibility, tab order, and that every interactive element, including the consultation modal's 20+ fields, is reachable and operable without a mouse.

SCREEN READER (NVDA)

80%

In progress. Confirmed interactive elements are announced with both a role and an accessible name, not read as plain text. Remaining passes to be completed and folded into a future revision of this report.

Methodology & Limitations

Automated scanning

axe DevTools, Chrome Lighthouse, and WAVE, cross-checked against each other — a live-DOM WAVE extension scan replaced an earlier online-scanner pass after it under-reported headings on a JS-rendered page, a good example of automated tools disagreeing and needing manual resolution.

Root-cause code review

Every fix traces to an actual line of source (shown earlier in this report), not a blind re-prompt. Several scanner flags were reviewed and deliberately left unfixed where the “correct” markup would have made real usability worse.

Audit conducted on rytglobal.com, a site the auditor co-built, as part of independent accessibility engineering practice. Report current as of August 2026; the NVDA pass will be finalized in a follow-up revision.
